Supplemental Table 2. STERGM model for link prediction. This is the Separable Temporal Exponential Random Graph Model of the variable that are associated with the formation of the hemodialysis clinic social network. We report the beta-coefficients which are the log-odds of the formation of link and the standard error of the coefficients as well as the *p* value. Edges is the log-odds of a participant forming a link with another participant independent of the other variables and represents the intercept of the model. Geometric Weighted Degree (GWDegree) is the log-odds of a participants with fewer links (i.e lower degree) to form a new link compared those participants with links (i.e. higher degree). Geometric edgewise shared pairs (GWESP) are the log-odds that participants are more likely to link if they already share a link in common with another participant. These effects geometrically diminish as the number of shared links decrease. Sociality represents the propensity of a participant forming a link with any other participant, Homophily represents the propensity of a participant to form a link with another participant with the same attribute. Tuesday, Thursday, Saturday dialysis shift (TTS). High School or less (< HS). Akaike Information Criterion (AIC). Bayesian information criterion (BIC).

| Switch 5 | 0.06 | 0.07 | | |

Supplemental Table 3. The effects of randomly reversing the result of transplant discussions on the transplant parameter. To examine the robustness of the model, we performed random data manipulations. We randomly changed participants who had transplant discussions to not having discussions and vice versa for five participants (10% of the data) and then 10 participants (20% of the data), and then we re-estimated the model on using these datasets. Each of these data manipulation procedures was performed five times.
